Measurements at different spatial scales

- Ex vivo/animal studies in vivo:
 - Standard electrophysiology
 - Ca²⁺ imaging
 - Voltage-sensitive dye (VSD) imaging
- Invasive animal/human measurements
 - Electrocorticography (ECoG)
- Noninvasive measurements
 - Electroencephalography (EEG)
 - Magnetoencephalography (MEG)
 - Magnetic resonance imaging (MRI)

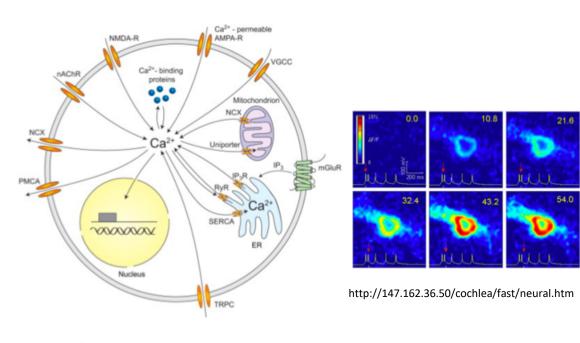

Electrophysiological recordings of neurons

- Current clamp: Measure membrane currents
- Voltage clamp: Measure membrane potential
 - In both methods, the cell membrane is typically pierced by a sharp electrode

- Patch clamp
 - Patch pipette tightly sealed to the cell membrane
 - Many types of techniques: Cell-attached patch, whole cell patch, inside-out patch, outside-out patch, etc.

Ca²⁺ imaging of neurons

- Based on membrane-impermeant Ca²⁺ indicator molecules/proteins
- High-resolution imaging of single neurons or imaging of a whole network of neurons
- Problems:
 - Temporal resolution not as high as in electrophysiological recordings
 - Ca²⁺ binding required
 - -> Indicators alter the intracellular Ca²⁺ signaling
 - Heavily affected by supra-threshold inputs, yet difficult to differentiate between successive spikes

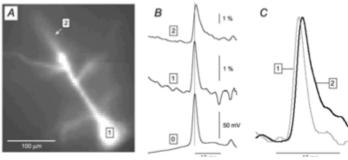

Grienberger, Christine, and Arthur Konnerth. "Imaging calcium in neurons." *Neuron* 73.5 (2012): 862-885.

VSD imaging of neurons

- Based on membrane-anchored voltage-indicating molecules
- Relatively high temporal resolution, typically limited by the speed of the microscope camera

• Problems:

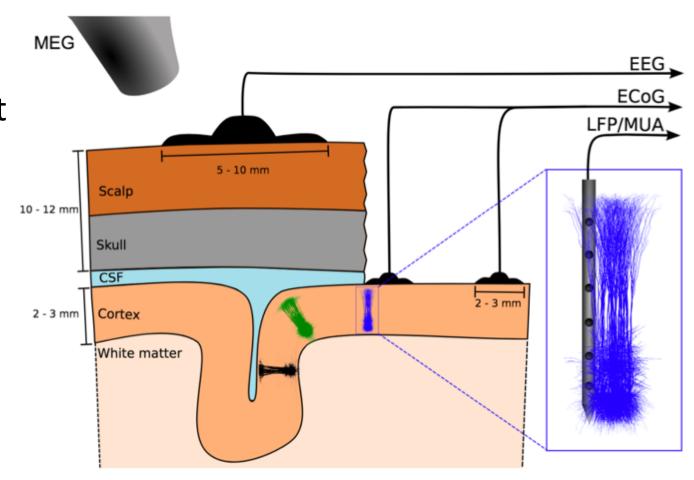

- Very sensitive to distance from the membrane
- Limited number of VSD molecules at the plasma membrane -> extensive averaging needed
- VSD molecules may anchor to internal membranes
- Large numbers of VSD molecules at the membrane may alter the dynamical functions of the membrane

Antic, Srdjan D. "Action potentials in basal and oblique dendrites of rat neocortical pyramidal neurons." *The Journal of physiology* 550.1 (2003): 35-50.

ECoG, EEG, MEG

- Based on electrical dipole properties of the neuron that affect the local field potentials (LFPs) and the magnetic fields
 - Current flows into the neuron at certain locations and out at other locations
 - Single-cell contributions small, but synchronized activity of thousands or millions of neurons can be observed

Hagen, Espen, et al. "Multimodal modeling of neural network activity: computing LFP, ECoG, EEG and MEG signals with LFPy2. 0." *bioRxiv* (2018): 281717.

Forward modelling of the LFPs

- Poisson equation: $\nabla \cdot (\sigma_{\rm e}(\mathbf{r}) \nabla \phi(\mathbf{r}, t)) = -C(\mathbf{r}, t)$
- Extracellular potential: $\phi(\mathbf{r},t) = \frac{1}{4\pi\sigma_{\rm e}} \frac{I(t)}{|\mathbf{r} \mathbf{r}'|}$
- Point source approximation: $\phi(\mathbf{r},t) = \frac{1}{4\pi\sigma_{\rm e}} \sum_{j=1}^{N} \sum_{n=1}^{n_j} \frac{I_{jn}^{\rm m}(t)}{|\mathbf{r} \mathbf{r}_{jn}|}$
- Line source approximation: $\phi(\mathbf{r},t) = \frac{1}{4\pi\sigma_{\rm e}} \sum_{j=1}^{N} \sum_{n=1}^{n_{j}^{\rm res}} I_{jn}^{\rm m}(t) \int \frac{1}{|\mathbf{r} \mathbf{r}_{jn}|} d\mathbf{r}_{jn}$

$$= \frac{1}{4\pi\sigma_{\rm e}} \sum_{j=1}^{N} \sum_{n=1}^{n_{j}^{\rm seg}} \frac{I_{jn}^{\rm m}(t)}{\Delta s_{jn}} \ln \left| \frac{\sqrt{h_{jn}^{2} + r_{\perp jn}^{2}} - h_{jn}}{\sqrt{l_{jn}^{2} + r_{\perp jn}^{2}} - l_{jn}} \right|$$

- Assumed a constant conductivity $\sigma_{\rm e}$
 - Not the case in EEG measurements

Hagen, Espen, et al. "Multimodal modeling of neural network activity: computing LFP, ECoG, EEG and MEG signals with LFPy2. 0." *bioRxiv* (2018): 281717.

Forward modelling of the EEGs

• When conductivity $\sigma_{\rm e}$ is not constant, alternative solutions for the Poisson equation

$$\nabla \cdot (\sigma_{\rm e}(\mathbf{r}) \nabla \phi(\mathbf{r}, t)) = -C(\mathbf{r}, t)$$

are needed

 $r_{s-1} \leq r \leq r_s$.

For forward modelling of the EEG signals, a simple head model can be

used to calculate contribution of

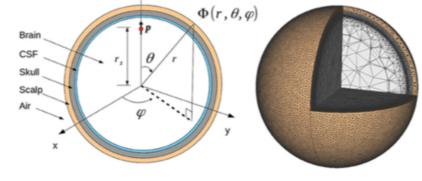

Radial dipoles:

Tangential dipoles:

$$\Phi^{1}\left(r,\theta\right) = \frac{p}{4\pi\sigma_{1}r_{z}^{2}}\sum_{n=1}^{\infty}\left[A_{n}^{1}\left(\frac{r}{r_{1}}\right)^{n} + \left(\frac{r_{z}}{r}\right)^{n+1}\right]nP_{n}\left(\cos\theta\right) \qquad \Phi^{1}\left(r,\theta,\varphi\right) = \frac{-p}{4\pi\sigma_{1}r_{z}^{2}}\sin\varphi\sum_{n=1}^{\infty}\left[A_{n}^{1}\left(\frac{r}{r_{1}}\right)^{n} + \left(\frac{r_{z}}{r}\right)^{n+1}\right]P_{n}^{1}\left(\cos\theta\right) \qquad r_{z} < r \leq r_{1},$$

$$\Phi^{s}(r,\theta,\varphi) = \frac{-p}{4\pi\sigma_{1}r_{z}^{2}}\sin\varphi\sum_{n=1}^{\infty}\left[A_{n}^{s}\left(\frac{r}{r_{s}}\right)^{n} + B_{n}^{s}\left(\frac{r_{s}}{r}\right)^{n+1}\right]P_{n}^{1}(\cos\theta)$$

$$r_{s-1} \leq r \leq r_{s},$$

 $\Phi^{s}(r,\theta) = \frac{p}{4\pi\sigma_{1}r_{z}^{2}} \sum_{n=1}^{\infty} \left[A_{n}^{s} \left(\frac{r_{s}}{r_{s}} \right)^{n} + B_{n}^{s} \left(\frac{r_{s}}{r} \right)^{n+1} \right] n P_{n}(\cos\theta) \qquad \Phi^{s}(r,\theta,\varphi) = \frac{-p}{4\pi\sigma_{1}r_{z}^{2}} \sin\varphi \sum_{n=1}^{\infty} \left[A_{n}^{s} \left(\frac{r_{s}}{r_{s}} \right)^{n} + B_{n}^{s} \left(\frac{r_{s}}{r_{s}} \right)^{n+1} \right] P_{n}^{1}(\cos\theta) \qquad \text{Næss, Solveig, et al. "Corrected four-sphere head model for EEG signals." Frontiers in human neuroscience 11 (2017):$ EEG signals." Frontiers in human neuroscience 11 (2017): 490.

Forward modelling of the MEG

Magnetic field from dipole p can be calculated as

$$\mathbf{B}_{\mathbf{p}} = \frac{\mu_0}{4\pi} \frac{\mathbf{p} \times \mathbf{R}}{R^3}$$

Relation between magnetic fields measured by M and H:

$$\mathbf{B} = \mu_0(\mathbf{H} + \mathbf{M})$$

• In biological tissue, M is small

Magnetic resonance imaging (MRI)

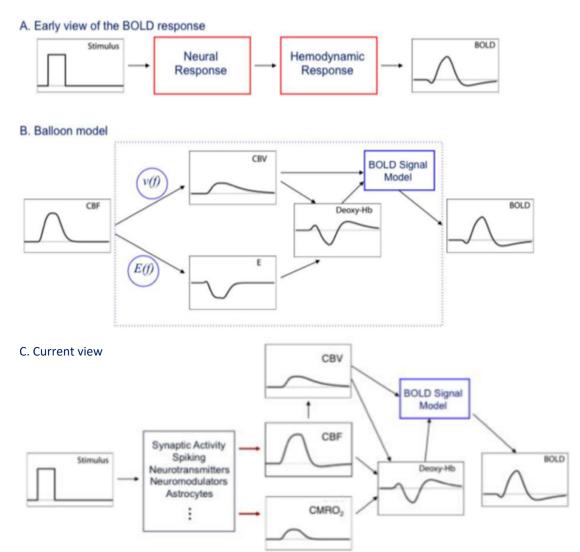

- Can be used to measure
 - Molecular diffusion -> diffusion tensor imaging (DTI)
 - Tissue composition —> structural MRI
 - Changes in oxygen saturation-dependent magnetism of hemoglobin (blood-oxygen-level dependent (BOLD) signal) -> functional MRI (fMRI)
- High spatial resolution (millions of data points in 3D), low temporal resolution (typically \sim 0.5 Hz)

BOLD signal is widely adopted but difficult to

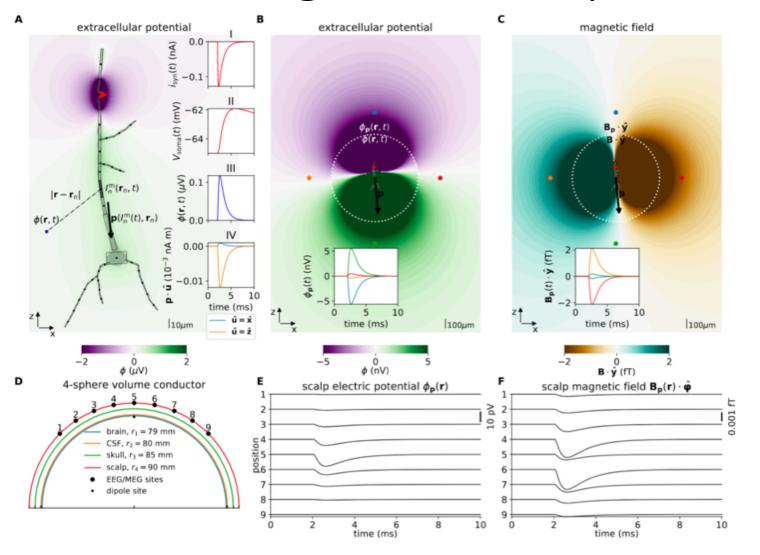

model

- The BOLD signals stem from magnetic properties of the deoxyhemoglobin
- Neural activation decreases oxygen extraction fraction (E)
 - This depends on cerebral blood flow (CBF) and volume (CBV) and on the cerebral metabolic rate of oxygen (CMRO₂)
